Important Instructions to examiners:

- 1) The answers should be examined by key words and not as word-to-word as given in the model answer scheme.
- 2) The model answer and the answer written by candidate may vary but the examiner may try to assess the understanding level of the candidate.
- 3) The language errors such as grammatical, spelling errors should not be given more Importance (Not applicable for subject English and Communication Skills).
- 4) While assessing figures, examiner may give credit for principal components indicated in the figure. The figures drawn by candidate and model answer may vary. The examiner may give credit for any equivalent figure drawn.
- 5) Credits may be given step wise for numerical problems. In some cases, the assumed constant values may vary and there may be some difference in the candidate's answers and model answer.
- 6) In case of some questions credit may be given by judgement on part of examiner of relevant answer based on candidate's understanding.
- 7) For programming language papers, credit may be given to any other program based on equivalent concept.

17648

Page 15 of 25

It is the cooling type continuous jacketed trough crystallizer. It is an example of scrapped surface crystallizer.

Construction:

It consists of a long open rectangular trough with a semi cylindrical bottom that is u shaped trough, of width 0.6m and length 3-6m. The trough is jacketed externally for circulating the coolant during operation. □ A spiral agitator rotating at about 7 rpm is incorporated in the trough in such a way that it is as close to the bottom of the trough as possible. It helps to transport crystals from one point to another point and doesn't allow crystals to settle at the bottom. At one end of the crystallizer an inlet for hot solution is provided. and at the other end, an overflow gate for the crystals and mother liquor discharge is provided, The function of spiral agitator include to scrap crystal, to lift and shower the crystal of uniform size, and to convey crystal from one end to the other end of equipment.

Working:

The hot concentrated solution is fed at one end of the open trough and flows slowly towards the other end of trough. Water is fed to the jacket in such a way that it flows in a counter current fashion with respect to the solution.

2

2

WINTER-17 EXAMINATION
Model Answer

Subject Title: Mass Transfer Operation

Subject code

17648

Page 16 of 25

The solution while flowing through the trough is cooled by heat transfer to water. Once the solution becomes super saturated crystals start forming and building. A spiral agitator keeps the crystal in suspension so that previously formed crystals grow instead of formation of new crystals. Ultimately the two phase mixture of crystals and liquor leaves the crystallizer through an overflow gate.

4.B b

Rate of drying curve :

Rate of drying curve is plotted with rate of drying on y-axis and moist. Content on x-axis.

Section AB of the curve represents the **warning up period** during which this temperature of the solid is becoming equal to the temperature of drying air. BC is straight line that to x-axis in presenting **constant rate** of drying during which the layers of water on the surface of solid is being evaporated. The section CE of the curve represents the **falling rate period** composing of first falling rate period CD and second falling rate period DE from point C onwards some dry patches have started forming on the surface of the solid. The rate of drying decreases for the unsaturated portion and hence rate for total surface

5-c	<p>Selection criteria for solvent selection in liquid-liquid extraction:</p> <ol style="list-style-type: none">1. Selectivity: The ratio of concentration ratio of solute to feed solvent in extract phase to that in raffinate phase is called selectivity factor. It is the measure of effectiveness of solvent for separating the constituents.2. Recoverability: As solvent should be recovered for reuse frequently by distillation, it should not form an azeotrope with extracted solute and for low cost recovery, relative volatility should be high.3. Distribution coefficient: Higher values are desirable as less solvent will then be required for given extraction duty.4. Density: The difference in densities of saturated liquid phases should be larger for physical separation.5. Insolubility of solvent: The solvent insoluble in original liquid solvent should be preferred and it should have high solubility for solute to be extracted, then small amounts of solvent are required.6. Chemical Stability: The solvent should be stable chemically and inert towards other components and should not be corrosive.7. Cost: The solvent should be cheap.8. The solvent should be non toxic, non flammable.9. Solvent should have low viscosity, freezing point, vapor pressure for ease in handling and storage.10. Interfacial tension: It should be high for coalescence of emulsions to occur more readily, as the same is of greater importance than dispersion.	<p>½ mark each for any 8</p>
5-d	<p>Optimum reflux ratio is an economic approach:</p> <p>Infinite reflux ratio requiring minimum number of plates and minimum reflux ratio requiring infinite number of plates is a workable system which requires finite stages for the desired degree of separation. At minimum reflux ratio as infinite number of plates are required, the fixed cost is also infinite while the</p>	<p>3</p>

WINTER-17 EXAMINATION
Model Answer

Subject Title: Mass Transfer Operation

Subject code

17648

Page 20 of 25

cost of heat supply to the reboiler and condenser coolant is minimum. As the reflux ratio is increased, the number of plates decreases and the fixed cost decreases at first, passes through a minimum and then increases as with higher reflux ratio the diameter of the column and sizes of reboiler and condenser increases. The operating cost increases continuously with reflux ratio as it is directly proportional to $(R + 1)$. At total reflux, though the number of plates are minimum, the cost of heat supply to reboiler and condenser coolant is maximum and also large capacity Reboiler and condenser are needed. The total cost which is the sum of the fixed cost and the operating cost also decreases to a minimum and then increases with reflux ratio. The optimum reflux ratio occurs at a point where the sum of the fixed cost and operating cost is minimum. As a rough approximation, **the optimum reflux ratio usually lies in the range of 1.1 to 1.5 times the minimum reflux ratio.**

	<p>finally bubbling through the liquid on the tray.</p> <p>SIEVE TRAYS</p> <p>Sieve trays are simply metal plates with holes in them. Vapour passes straight upward through the liquid on the plate. The arrangement, number and size of the holes are design parameters.</p> <p>VALVE TRAYS</p> <p>In valve trays, perforations are covered by liftable caps. Vapour flows lifts the caps, thus self creating a flow area for the passage of vapour. The lifting cap directs the vapour to flow horizontally into the liquid, thus providing better mixing than is possible in sieve trays.</p>

2. Draw the equilibrium curve and diagonal with the help of x-y data.
3. Draw the operating line of rectifying section through point(x_D, x_D) on diagonal with intercept equal to $x_D / (R+1)$
4. Draw feed line on equilibrium curve based on feed conditions.
5. Draw operating line of stripping section through (x_W, x_W) on diagonal and point of intersection of feed line and rectifying section line.
6. Starting from (x_D, x_D) on diagonal, draw a horizontal line to meet the equilibrium curve, drop a vertical to meet the operating line.
7. Proceed this way, constructing the triangles between equilibrium curve and operating line of rectifying section, till we are above the point of intersection . Once we cross this point of intersection, construct the triangles between equilibrium curve and operating line of the stripping section
8. Proceed in the same manner till we reach across the point (x_W, x_W)
9. Count the number of triangles between x_D and x_W . Each triangle represents a theoretical plate.

If numbers of triangles are n, then (n-1) represents the number of theoretical plates in the column.

(i) **Milk powder** – Spray dryer

Reason: Milk can be sprayed in form of fine spray in hot & dry air in counter current direction in spray chamber to get dried milk powder.

(ii) **Wet lumpy solids** – Tunnel dryer / Tray drier

Reason : Wet lumps can be placed on trays which can be loaded on trucks which can be put in tunnel in which hot air is flowing in counter current direction.

(iii) **Free flowing material** – Rotary dryer

Reason : Free flowing material is allowed to flow down in a slightly inclined cylinder which is rotating material fed is advanced through dryer by gravity in opposite direction to hot air/ flue gases admitted at bottom to flow towards top of cylinder. Spiral flights help to keep material in suspension in flow of hot & dry air.

(iv) **Pharmaceutical products** – Tray dryer

	Reason : relatively cheap, low maintenance cost , no loss of product during drying , Easy in cleaning.	1
6-c	<p>Hydrodynamics / pressure drop characteristics in packed column:</p> <p>In a packed column there are two flows flowing in counter current direction. Liquid fed at the top of column flows down the column through the void spaces in the packings, the same time gas mixture is forced up through the void spaces by using a blower or a compressor. To maintain flow of gas, pressure at the top must be less than that at the bottom. In packed column as same channels are available for liquid down flow & gas up flow, the gas pressure drop is a function of both phase flow rates & is important in design of packed column.</p> <p>The variation of pressure drop with gas velocity is plotted on log-log graph as shown in fig.</p> <div style="text-align: center;"> <p>A log-log plot showing the relationship between Log ΔP (Y-axis) and Log Vg (X-axis). The plot contains three curves: - 'Wet Packing': The lowest curve, which starts as a straight line and then curves upwards more steeply. - 'Dry Packing': A middle straight line parallel to the initial part of the Wet Packing curve. - 'Flooding Point Y': The uppermost curve, which also starts as a straight line and then curves upwards very steeply. A horizontal arrow points from 'Loading point X' on the right to the 'Dry Packing' curve. Another horizontal arrow points from 'Flooding Point Y' on the right to the 'Flooding Point Y' curve.</p> </div> <p>In case of dry packing, the relationship between pr.drop and gas velocity is represented by a straight line indicating that pressure drop is proportional to $G^{1.8-2}$. For wet packing, the relationship is indicated by straight line, but for a</p>	2

	<p>given velocity, pressure drop will be more than that for dry packing.</p> <p>With the liquid flow down the tower at low and moderate gas velocities, pr.drop is proportional to 1.8^{th} power of gas velocity. Up to point X the amount of liquid held up in packing is constant. At point X the gas flow begins to impede the down flow of liquid and local accumulation of liquid appears here and there in packings.</p> <p>As the gas velocity increases further liquid hold up progressively increases due to which free area for gas flow becomes smaller and pressure drop rises much more quickly. At gas flow rates beyond Y, pr.drop rises very steeply. At point Y, entrainment of liquid by gas leaving the top of tower increases and tower is then said to be flooded. The gas velocity corresponding to the flooding conditions is called as flooding velocity.</p>	3
